

## LINE LAYOUT AND OPERATION SCHEME

The line is y-shaped, composed with a main central segment plus two branches. For each segment, a length, a number of stops and a number of intersections are defined for each segment and sense. These parameters are equal for both senses in every segment, while stops and intersections are uniformly distributed along the segment length.

|                         | A     | B1    | B2    |
|-------------------------|-------|-------|-------|
| Segment distance (km)   | 8.750 | 2.975 | 4.600 |
| Number of stops         | 22    | 8     | 13    |
| Number of intersections | 61    | 21    | 26    |

Table 1. Line layout key parameters.

Operation schemes are differentiated between conventional and variable capacity. As conventional convoys run the corridor conserving the original convoy configuration with a constant convoy unit length, modular variable-capacity convoys apply two levers to generate a better spatial offer-demand fit. First, convoy splits and reassembles at the bifurcation to operate the two branches at the same headway, but reducing the capacity. Secondly, if the required number of pods for branch service is inferior to the required number of pods for main trunk service, a quantity of pods is allowed to split and keep operating the main segment in exclusivity.

Figure 1. Line layout.

Figure 2. Operation scheme for S0 – S1 – S2 (from left to right).

| Relative O/D (%) | A     | B1   | B2   |
|------------------|-------|------|------|
| A                | 74.00 | 4.10 | 4.10 |
| B1               | 4.10  | 1.50 | 0.00 |
| B2               | 4.10  | 0.00 | 8.10 |

## VEHICLE PARAMETERS

| Parameter                    | Modular pod | Minibus | Midibus | Standard |
|------------------------------|-------------|---------|---------|----------|
| Strategy                     | S1 – S2     | S0.1    | S0.2    | S0.3     |
| Vehicle Length (m)           | 3           | 6       | 9       | 12       |
| Weight (kg)                  | 2,550       | 4,600   | 16,000  | 20,000   |
| Capacity C (pax)             | 12          | 18      | 44      | 86       |
| Cons. factor $f_c$ (kW-h/km) | 0.17        | 0.31    | 1.09    | 1.36     |

|                               |         |         |         |         |
|-------------------------------|---------|---------|---------|---------|
| Vehicle price $C_{veh}$ (EUR) | 250,000 | 357,000 | 433,000 | 592,000 |
| Battery capacity $B$ (kW-h)   | 55      | 99      | 345     | 431     |

Table 2. Tested vehicle parameters.

## MOVEMENT PARAMETERS

| Parameter                                      | Value                  | Units   |
|--|------------------------|---------|
| Cruise speed ( $v_c$ )                         | 50                     | km/h    |
| Average acceleration ( $a_v$ )                 | 1.10                   | $m/s^2$ |
| Standard deviation acceleration ( $a_\sigma$ ) | 0.30                   | $m/s^2$ |
| Maximal acceleration ( $a_{max}$ )             | 2.00                   | $m/s^2$ |
| Traffic light green phase (G)                  | 30                     | s       |
| Traffic light red phase (R)                    | 30                     | s       |
| Unit boarding time ( $\tau_b$ )                | 3.75                   | s       |
| Unit alighting time ( $\tau_a$ )               | 1.90                   | s       |
| Daily operation time                           | 18                     | h       |
| Daily non-operative time                       | 6                      | h       |
| Minimum headway ( $H_{min}$ )                  | 3                      | min     |
| Headway  | 1 - 2 - ... - 10       | min     |
| Total demand                                   | 150 - 300 - ... - 3000 | pax/h   |
| Slack time                                     | 0 - 3 - 6              | min     |

## UNIT COSTS

|                        | S0.1        | S0.2        | S0.3         | S1          | S2          |
|------------------------|-------------|-------------|--------------|-------------|-------------|
| Vehicle Type           | 6-meter bus | 9-meter bus | 12-meter bus | 3-meter pod | 3-meter pod |
| $\$_L$ (EUR/km-h)      | 0.96        |             |              |             |             |
| $\$_V$ (EUR/veh-km)    | 0.40        | 0.73        | 0.95         | 0.20        |             |
| $\$_M$ (EUR/veh-h)     | 15.17       | 16.41       | 18.09        | 14.48       |             |
| $\$_{fc}$ (EUR/chrg-h) | 6.68        |             |              |             |             |
| $\$_{sc}$ (EUR/chrg-h) | 2.61        |             |              |             |             |
| $\$_B$ (EUR/veh-h)     | 0.32        | 1.12        | 1.40         | 0.18        |             |

Table 4. Simulation unit costs.

The model has been implemented in a Y-shaped corridor with a main trunk of 8.75 km and two branches of 2.975 km and 4.60 km respectively. We have tested different levels of demand with the same spatial distribution, where 74% of trips have the central corridor as origin and destination, while the rest have at least one extreme in the branches. In-vehicle travel time (IVTT) and waiting time are weighted by 1 and 2.1 respectively and affected to a value of time of 12.5 EUR/pax-h. All bus typologies are assumed to be automated, that is, no drivers are needed. The kinematic parameters of the bus, the characteristics of the bus corridor and the proxies of the system are defined in the following link. The simulation is run ten times for each scenario.
